Deposits of sand, gravel, and cobbles extend from the top of the mesa to the river. These deposits were likely transported by water and deposited during floods. The deposits are similar to those found in the surrounding area.

The map shows the distribution of different types of deposits, including alluvial fans, river channels, and terrace deposits. The map includes a legend that explains the different symbols used to represent the deposits.

The map is useful for understanding the depositional history of the area and for identifying potential locations for future deposits. It can also be used to identify areas that may be at risk for flooding or erosion.

The map was created using geographic information system (GIS) data and is available for download from the United States Geological Survey (USGS) website.
